

Ticket A2T8

The Manager has alerted us that some owncloud users have lost their data. Users owncloud01 and owncloud20 were specifically mentioned.

Step 1 Debugging:

First we check if the database is accessible by connecting to db-d and using either

```
mariadb
```

or

```
mysql
```

both mariadb and mysql seem to be ok

Step 2 Deeper Debugging:

We log into mysql to double check all the data is still there.

```
sudo mysql -u root -p
```

After inputting our password we navigate to the owncloud database.

```
show databases;
```

```
use owncloud;
```

We then check some relevant tables for any clues as to what happened.

```
# First we check all the users are still ok
```

```
select * from oc_users;
```

```
# Then we check if theres been any files changes.
```

```
select * from oc_filecache \G;
```

```
# We are specifically looking for two things
```

```
# First is if the owncloud log file has been updated.
```

```
# Then we want the newest files modified date.
```

```
select * from oc_filecache where name like '%.log%' \G;
```

```
select * from oc_filecache order by mtime asc \G;
```

These commands show us that our log file has not updated since june 1st while we have new files that were modified at june 11th 11:30 pm

Additionally all the default files were also modified at the same time.

From this and the lack of other files we can conclude that all of our users files were wiped from owncloud.

And because we didn't have a backup system setup with owncloud those files are completely lost.

Step 3 Post mortem

Following this attack we need to add another backup system that protects the users owncloud directory. Our previous backup system was created before we fully setup owncloud causing us to forget to protect it properly.

Now we know we have to protect `/var/www/owncloud/` folder with hourly backups when ever a file changes.
